Rothamsted Insect Survey

L. R. Taylor and R. A. French

L. R. Taylor and R. A. French (1970) *Rothamsted Insect Survey* ; Rothamsted Experimental Station Report For 1969 Part 2, pp 168 - 185 - DOI: <https://doi.org/10.23637/ERADOC-1-34869>

Rothamsted Insect Survey

L. R. TAYLOR and R. A. FRENCH

Suction traps

Three new traps operated in 1969, at the Rosewarne Experimental Horticultural Station, Camborne, in Cornwall, England, at the Welsh Plant Breeding Station, Plas Gogerddan, Nr. Aberystwyth, Wales, and at the Department of Agriculture and Fisheries for Scotland, East Craigs, Edinburgh 12, Scotland. The weekly bulletins listing 11 trap counts of 34 species, or groups, of aphids of economic interest was maintained with only one hiatus, during the third and fourth weeks of July when each week comprised only four days because full catches were too large to count in time to be included in the bulletin. This year the airflow characteristics of the trap were investigated and next year the volumetric air sample will be halved during July and August to lessen the risk of similar oversampling. The converse problem, that of increasing the sample size during April and May to increase sensitivity when incoming migrants are infesting crops, has proved to be less tractable because of the internal resistance of the trap at high air speeds; another attempt will be made to solve this problem during the coming season. It is hoped to complete the east/west transect next year with traps near Exeter, Bristol and Wageningen in Holland.

These tables are given here to publish records quickly, the final table being completed just in time for press. It may be possible to comment on them in Part 1 of the Report which is compiled later. The tables contain the same species as the bulletins. To save space, counts are given per 4-week period using the 'standard' weeks devised to coincide from year to year for convenience in analysis; the bulletin weeks are 'working' weeks from Monday through Sunday, chosen for convenience in despatching and sorting catches. The second trap at Rothamsted, formerly referred to as Rothamsted Farm, has been omitted from both bulletins and table to save space. Its function is entirely experimental and its adds little to the information on distribution on a large scale. A few days have been lost by accident or breakdown but, thanks to the lively co-operation of the operators and other members of staff to whom we are deeply indebted, there are no serious gaps in the record. Zero catches are left blank in the table for simplicity.

Light traps

In the *Rothamsted Report for 1968*, Part 1, 210–213, the annual catch of 26 species of moths of economic interest from light traps at 32 sites in Great Britain during 1967, and for some of these sites in 1966 and 1965 were tabulated. The catches of the same 26 species at sites in 1968 are given in Table 2 and those for 1967 repeated for comparison.

ROTHAMSTED INSECT SURVEY

Many more traps are now in operation, but only those that operated throughout the year are included in the table. Unlike the aphid records, it is not possible to publish these catches in the year they are obtained because most of the identification is done by voluntary workers and hence cannot be done immediately. Light traps give only a relative sample because their efficiency is subject to the behavioural response of the insect, so the catches of different species cannot be compared until the relative efficiency of the trap for the species has been assessed. At present, only the differences between sites and years can be usefully considered. The sites, which have been numbered sequentially as they began to operate, are arranged in latitude sequence, north to south, in the table. The species have been arranged according to their preferred latitude, north on the left to south on the right. The distribution of some species is erratic, and all are affected by the immediate environment of the trap, which ranges from urban streets through farmland to uncultivated moorland. Nevertheless, the latitudinal limits of some species are clearly defined and this may help to locate likely outbreak areas when we have more seasons' distributions. It is striking that the recognised pest species are not necessarily widespread nor generally common, some species being restricted to a fairly narrow band of latitudes. The spatial distribution of nearly all species in 1968 closely resembles that in 1967, except for *Plusia gamma*, an immigrant, *Gortyna micacea* and *Alsophila aescularia*, all of which were more common in 1968 than in 1967. Dashes indicate missing records; 0s record zero counts.

TABLE 1 *The Rothamsted Insect Survey—Suction Traps* is on pages 170–176.

TABLE 2 *The Rothamsted Insect Survey—Light Traps* is on pages 178–185.
