## Rothamsted Insect Survey Fourth Report With a Comment on the Neuroptera by J. Bowden

**L. R. Taylor and R. A. French**

L. R. Taylor and R. A. French (1973) *Rothamsted Insect Survey Fourth Report With a Comment on the Neuroptera by J. Bowden* ; Rothamsted Experimental Station Report For 1972 Part 2, pp 182 - 211 - DOI: <https://doi.org/10.23637/ERADOC-1-34695>

## Rothamsted Insect Survey

### Fourth Report

L. R. TAYLOR and R. A. FRENCH

With a comment on the Neuroptera by J. BOWDEN

#### Suction traps

Aphid bulletins were issued weekly from 24 April 1972 (Bulletin No. 1) to 29 October (Bulletin No. 28). Of the 32 aphid taxa listed in Bulletin No. 1, 1968, 23 remain unchanged. *Neomyzus circumflexum* (Buckton) and *Eucallipterus tiliae* (Linn.) have been deleted; *Phylaphis fagi* (Linn.), *Schizoneura (Eriosoma) ulmi* (Linn.), *Hyperomyzus lactucae* (Linn.) and *Dysaphis plantaginea* (Pass.) have been added. The *Amphorophora* spp. are now separated but only *A. rubi* (Kalt.) is listed. *Aphis fabae* (Scop.) is listed as *Aphis fabae* group; similarly, *Myzus persicae* (Sulz.) is now listed as *M. persicae* group, *M. certus* being separated later. *Aphis* spp. now includes *A. nasturtii* Kalt., *A. idaeii* Van der Goot and *A. frangulae* Kalt. Spring specimens of *Rhopalosiphum insertum* (Walk.) and *R. padi* (Linn.) were not adequately separated until 1971. *Pemphigus* spp. contains species currently inseparable from *bursarius*.

Catches from Zeeland, Broom's Barn and Aberystwyth were mainly identified at the site by D. Hille ris Lambers of Bladluisonderzoek T.N.O., G. D. Heathcote of Broom's Barn and J. A'Brook of the Welsh Plant Breeding Station. H. L. G. Stroyan of M.A.F.F. Plant Pathology Laboratories and V. F. Eastop of the British Museum (Natural History) confirmed difficult determinations and J. A. T. Woodford of Cambridge University separated *M. persicae* from *M. certus* and winged fundatrigeniae from spring migrants of *M. persicae*.

The same 32 aphid taxa that appeared in the weekly bulletin are listed in Table 1 a-h.

The bulletin sent out on Friday lists aphids caught between five and 12 days previously, except Zeeland and Copenhagen that appear a week late. This timing is determined by the postal service and is unlikely to be improved. The bulletin covers working weeks, Monday to Sunday. Published results (Table 1) are in four-week periods from Standard Week No. 13 to No. 44, 26 March to 4 November, as in 1971. The Standard Weeks, listed in Table 4, remain constant from year to year by the exclusion of 29 February and 31 December.

The East Craigs trap, burned down in 1971, has been replaced; the Zeeland trap has been moved 8 km north to a new site, rather less exposed than the previous one, and worked throughout the season. The new trap at Shardlow, near Derby, began trapping on 20 March. Additional traps at Garston, Hertfordshire, and at Rothamsted Farm (two traps) are not included in the bulletin nor in Table 1.

Whilst the Copenhagen trap occasionally produced numbers well outside the range of the British traps, it is not yet apparent that either the overall sample size, or the species composition, differ greatly.

Sample volumes were halved at Shardlow, Broom's Barn, Rothamsted Tower, Silwood Park and Wye from 16 July to 6 August, at Rosemaund from 24 July to 7 August and at all traps, except Zeeland from 25 September to 22 October. The bulletin and Table 1 are corrected to full sample volume.

In Table 1 there are no missing values; a blank records a zero catch.

## ROTHAMSTED INSECT SURVEY

Neuroptera, including the aphid predators, have been identified from 1970, 1971 and 1972 catches and the commonest species, *Chrysopa carnea*, is listed in Table 3a with a discussion of this and the rarer species, listed in Table 3b, by J. Bowden (p. 209). It is unlikely that all specimens of the very small species were recovered in these years; a more careful search will be made in future.

In Table 3 dashes indicate no record; a blank records a zero catch.

### Light traps

Tables 2 a-d give the total annual catches during 1970 and 1971 of the same 31 pest, or migratory, Lepidoptera as in *Rothamsted Report for 1971*, Part 2. Of the 68 sites with a full year's sample in 1970, 52 also completed 1971, 20 new sites makes a total of 72 in the table. At the end of 1972 129 traps are operating.

The sites in Table 2 are arranged in sequence from north to south and the species are in the same order as in previous years. Zero catches are recorded as 0; dashes indicate no records.

Voluntary workers again operated most of the traps and identified many of the insects; for this we are most grateful.

### Table 1 (a-h)

*The Rothamsted Insect Survey—Suction Traps: four-weekly total catches of aphids of economic, or other, interest reported in the Weekly Bulletin 1972*

Pages 184-199

### Table 2 (a-d)

*The Rothamsted Insect Survey—Light Traps: annual records of moths of economic, or other, interest for 1970 and 1971*

Pages 200-207

### Table 3 (a-b)

*The Rothamsted Insect Survey—Suction Traps: four-weekly total catches of Chrysopa carnea and the three years' annual total of other lacewings for 1970, 1971 and 1972 identified by J. Bowden*

Pages 208-209

## ROTHAMSTED REPORT FOR 1972, PART 2

### Neuroptera in the Rothamsted Insect Survey, 1970–72

There are 29 species of Hemerobiidae and 14 species of Chrysopidae in the British fauna. The suction traps have so far caught 13 species of Hemerobiidae and seven of Chrysopidae.

Eight species have been recorded one to three times only. These are: Hemerobiidae: *Hemerobius atrifrons* McLachlan, Elgin, 3 September 1971; *Symplocopteryx elegans* (Stephens), Silwood Park, 29 July 1972; *S. pygmaeus* (Rambur), Silwood Park, 19 July and 17 September 1971 and Shardlow, 19 August 1972; *Kimminsia killingtoni* Morton, Elgin, 20 and 21 July 1971. Chrysopidae: *Chrysopa flavifrons* Brauer, Hereford, 13 August 1972; *C. phyllochroma* Wesmael, Silwood Park, 3 July 1970; *C. septempunctata* Wesmael, Silwood Park, 26 June and 28 July 1970; *C. vittata* Wesmael, Silwood Park, 1 August 1970. Other species are in Table 3.

The outstanding feature is the abundance of *Chrysopa carnea* Stephens. It is the only species found in the most northerly traps; elsewhere it outnumbers all other species of *Chrysopa* combined by over 100 to 1. First appearances of *C. carnea* in all three years have been in the most southerly sites, particularly Wye and Silwood; Newcastle is consistently the earliest of the northern traps. The Elgin trap produces, in a short season, numbers far in excess of Dundee, Newcastle and High Mowthorpe and, in the period from week 41 to week 44, may catch more than all but the most productive southern traps. It is known (Macleod, 1967; Tauber & Tauber, 1969, Tauber *et al.*, 1970) that, in controlled conditions, reproductive diapause in adult *C. carnea* can be induced by a daily photoperiod of 12 hours and maintained for a long time by a daily photoperiod of 10 hours. One of the indications of diapause is the appearance of red-brown colour in the adults. The first occurrence of adults showing diapause colour has consistently been in weeks 39 and 40 when daily photoperiod changes, from more than, to less than 12 hours. A more striking phenomenon is the virtual disappearance of *C. carnea* from all traps in each year between weeks 43 and 45. In week 42, daily photoperiod (sunrise to sunset) is everywhere above 10 hours. During week 43, photoperiod decreases to about 9½ hours at Elgin (approximately 58° N) while still 10 hours or more at the most southern latitudes, 50°–52° N, which themselves receive less than 10-hour photoperiod during week 44. At Elgin the last substantial catches occur during week 43 and in the south during week 44. From week 45 few adults are taken until the following spring. These observations confirm the importance of a 12-hour photoperiod in diapause induction and also suggest that cessation of flight activity, caused by a critical photoperiod of about 10 hours, indicates the commencement of sustained and synchronised diapause and hibernation. In spring and early summer the beginning of flight activity must be related to some other environmental factor, possibly temperature, since 10-hour and 12-hour photoperiods are attained in weeks 8 and 12, respectively.

The Hemerobiidae are trapped in comparatively small numbers. *Kimminsia killingtoni*, taken twice at Elgin, is a northern species, the others are all generally regarded as more widely distributed. Greatest numbers are usually trapped in the south, exceptions being *Hemerobius stigma* Stephens which was particularly common at Elgin in 1971, and *Hemerobius atrifrons* taken once at Elgin but recorded in the literature as commonest in the south of England.

(J. Bowden)
