Rothamsted Insect Survey

Fourteenth Annual Summary

L. R. TAYLOR, I. P. WOIWOD, E. D. M. MACAULAY, MAUREEN J. DUPUCH and
JOAN NICKLEN

With a comment on the Neuroptera by J. BOWDEN

Suction traps 1982

Daily samples were collected from 13 April to 4 November 1982 and the *Aphid Bulletins* were issued weekly from 13 April (*Bulletin* No. 1) to 4 November (*Bulletin* No. 30). The 33 aphid taxa listed in Table 1 (a-h) are those in the *Aphid Bulletin*.

Dr L. A. D. Turl and colleagues at the Department of Agriculture and Fisheries for Scotland (DAFS), East Craigs, were responsible for the operation of traps at Elgin, Dundee, East Craigs, Pathhead, Ayr and also Stirling. The trap at Rainham only operated from 10 April to 15 July; it only appeared on *Bulletins* up to 15 July and in Table 1 (a-d). Traps in Holland continued to operate, but records do not appear on the *Bulletins* nor in Table 1. Suction traps sampling at 5ft (1.5 m) were operating at East Craigs, Ingraston, Hereford and Rothamsted Tower; records for these do not appear on *Bulletins* nor in Table 1.

Samples from Aberystwyth were identified by Mr J. A'Brook and Mr H. Evans of the Welsh Plant Breeding Station; Dr G. D. Heathcote of Broom's Barn Experimental Station identified aphids from Broom's Barn. The samples from the Scottish traps were identified by Dr L. A. D. Turl, Dr D. A. Cooper, Mr D. B. Cole and Mr R. Burns of the Department of Agriculture and Fisheries for Scotland, East Craigs. We wish to thank Dr H. L. G. Stroyan of the Ministry of Agriculture, Fisheries and Food, Harpenden Laboratory, for helping with taxonomic problems.

The *Bulletin*, despatched each Friday, lists aphids caught between 5 and 12 days earlier. This timing is dictated by the postal services.

The *Bulletins* cover the working week Monday to Sunday. Table 1 is for standard 4-week periods constant from year to year (see *Rothamsted Report for 1972*, Part 2, 211, Table 4). *Bulletin and standard weeks do not correspond*.

Sample volumes were halved at various sites as follows:—Kirton and Littlehampton from 8 June to 23 June, Preston from 8 June to 23 June, and from 23 September to 20 October, Shardlow, Writtle and Wye from 8 June to 18 October, Long Ashton and Silwood from 8 June to 19 October, Rainham from 9 June to 15 July, Hereford from 9 June to 23 June and from 8 July to 26 September. In addition, when numbers were high, catches were sub-sampled in the laboratory to reduce the pressure of work. The weekly *Bulletins* and Table 1 (a-h) are corrected to full volume sample.

In Table 1 (a-h) there are no missing values, a blank records a zero catch.

Of particular note during 1982 were the exceptionally large numbers of cereal aphids in traps from eastern Scotland during July and August. Three species were involved, *Metopolophium dirhodum*, *Rhopalosiphum padi* and *Sitobion avenae*, with numbers of *M.*

ROTHAMSTED REPORT FOR 1982, PART 2

dirhodum in the traps reaching levels only exceeded previously in 1979 in eastern and midland England. It is thought that this large population build-up occurred too late to cause economic damage to spring barley in Scotland.

Light traps

Table 2(a-f) gives the annual catches during 1980 and 1981 of the same pest, or migratory Lepidoptera as in previous years.

Ninety sites completed the 364-day sample for 1981.

The sites in Table 2 are arranged in sequence from north to south and the species are in the same order as in previous years. Zero catches are recorded as 0; dashes indicate missing records.

Once again voluntary workers operated most of the traps and identified many of the insects; we are most grateful for their help.

Neuroptera in the Rothamsted Insect Survey, 1979-82

Three species have been added to the list trapped (*Rothamsted Reports*, for 1972, Part 2, 208-210; 1975, Part 2, 126-128; 1978, Part 2, 171-173); *Wesmaelius concinnus* taken once at Littlehampton in 1979 and once at High Mowthorpe in 1982; *Micromus angulatus* once at Silwood in 1982 and *Chrysopa perla* taken once at Shardlow and once in the 1.2 m trap at Hereford, both in 1982. *Hemerobius pini* was taken again, one at Elgin in 1980. The Survey traps have now taken 18 of the 29 British species of Hemerobiidae and 9 of 15 Chrysopidae.

The species recorded above illustrate an interesting feature, the relative frequency with which species are caught. Some species, such as *M. angulatus* and *H. pini* are very local, or rare, or both, so it is not surprising that they are trapped infrequently. Others such as *W. concinnus* and *C. perla* are common and might be expected to be trapped more often than they are. However, many Neuroptera are habitat specialists, although in their habitats larvae may feed on a variety of prey. *W. concinnus* is confined to conifers while *C. perla* is predominantly an insect of deciduous woods. The fact that Survey traps are sited in more or less open areas may result in infrequent catches of species such as *W. concinnus* and *C. perla* but dispersive propensity is probably a more important factor. *Hemerobius stigma* is a conifer frequenting species but is one of the more commonly caught Hemerobiids and *Chrysopa carnea* is common in deciduous woodland, but many other habitats as well and is the most abundantly trapped of all Neuroptera. All four British species of *Symppherobius* are known to occur at Rothamsted and two of them, *S. elegans* and *S. pygmaeus*, which are common on oaks, are taken, often in numbers, in light traps but are very rare in suction trap catches, none ever having been caught in either suction trap at Rothamsted. Similarly, *Micromus paganus* is a very common insect but trapped very infrequently by suction traps. By contrast *Hemerobius humulinus*, *Wesmaelius betulinus* and *W. subnebulosa* are also found on deciduous trees, including oaks, and are among the commonest Hemerobiids in suction-trap catches. The differing catches of common species in the Survey suction traps presumably reflect species differences in dispersal behaviour.

Trap records, which now extend over 13 years, suggest, at least for those species trapped most often, that Neuroptera are insects pre-eminently of south and east England. Even *C. carnea* is markedly less common in traps north of Rothamsted and west of Littlehampton. *C. carnea* overwinters as adults, these becoming active in April and May and giving rise to the next generation of adults in July and early August. The difference between south-eastern and other traps is greatest up to week 32, even later in the most northern traps, suggesting that there is a summer dispersal from south-east

ROTHAMSTED INSECT SURVEY

England, as in some aphid species. Although other Chrysopidae and all Hemerobiidae are trapped in very much smaller numbers than *C. carnea*, data suggest the same pattern of distribution and dispersal with the possible exception of *H. stigma* which occurs as frequently at Elgin as in many of the southern traps. (*J. Bowden*).

See Table 3 (a) and (b) on following pages.
