### ORIGIN, SCOPE, AND PLAN,

OF THE

### ROTHAMSTED EXPERIMENTS.

The following statement of the origin, scope, and plan, of the Rothamsted Investigations, was drawn up in answer to a circular letter issued by a Committee appointed to arrange for the commemoration of the twenty-fifth anniversary of the establishment of the First Experimental Station in Germany (Möckern), which was held in Leipzig in September 1877. The precise form of the statement depended on the order and form of the questions to which it is an answer. It has already been published in German, almost in full, with the series of reports of other Experimental Stations, which was issued at the time of the Jubilee Meeting. It has been thought that it would be of some interest as an introduction to the Memoranda of the Plan and Results of the Field Experiments, &c., annually issued at Rothamsted, and which here follow it. To the general statement, which, with a few slight alterations correcting it up to date, is given in the form in which it was originally drawn up, are appended lists of the titles of all the papers already published, with full reference to the Journals in which they appeared.

Mr. Lawes was the founder of the Rothamsted Experimental Station. He commenced experiments with different manuring substances, first with plants in pots, and afterwards in the field, soon after entering into possession of his hereditary property at Rothamsted<sup>3</sup> in 1834. The researches of De Saussure on vegetation were the chief subjects of his study to this end. Of all the experiments so made, those in which the neutral phosphate of lime, in bones, bone-ash, and apatite, was rendered soluble by means of sulphuric acid, and the mixture applied for root-crops, gave the most striking results. The results obtained on a small scale in 1837, 1838, and 1839, were such as to lead to more extensive trials in the field in 1840 and 1841, and subsequently.

In 1843 more systematic field experiments were commenced; and a barn, which had previously been partially applied to to laboratory purposes, became almost exclusively devoted to agricultural investigations. The foundation of the Rothamsted Experimental Station may be said to date from that time (1843).

The Rothamsted station has up to the present time been entirely disconnected from any external organization, and has been maintained entirely by Mr. Lawes. He has further set apart a sum of £100,000, and certain areas of land, for the continuance of the investigations after his death.

In 1854-5 a new laboratory was built, by public subscription of agriculturists, and presented to Mr. Lawes, in July 1855, from which date the old barn-laboratory was abandoned, and the new one has been occupied.

From June 1843, up to the present time, Dr. J. H. Gilbert has been associated with Mr. Lawes, and has had the direction of the laboratory.

The number of assistants and other helps has increased from time to time. At first only one laboratory man was employed; but very soon a chemical assistant was necessary, and next a computer and record-keeper.

During the last twenty-five years the staff has consisted of— One or two, and sometimes three, chemists.

Two or three general assistants. One of these is usually employed in routine chemical work, but sometimes in more general work. The chief occupation of the general assistants is to superintend the field experiments—that is, the making of the manures, the measurement of the plots, the application of the

manures, and the harvesting of the crops; also the taking of samples, the preparation of them for preservation or analysis, and the determinations of dry matter, ash, &c. These assistants also superintend any experiments made with animals. There are now about 30,000 bottles of samples of experimentally-grown vegetable produce, of animal products, of ashes, or of soils, stored in the laboratory.

A botanical assistant is also occasionally employed, with from three to six boys under him, and with him is generally associated one of the permanent general assistants, who at other times undertakes the botanical work.

Two or three (for some time past three) computers and record-keepers have been occupied in calculating and tabulating field, feeding, and laboratory results, copying, &c.

One, and sometimes two, laboratory men are employed.

Besides the permanent laboratory staff, chemical assistance is frequently engaged in London, or elsewhere; and, in this way, for some years past, Mr. R. Richter, of Berlin, has been almost constantly occupied with analytical work sent from Rothamsted.

The field experiments, and occasionally feeding experiments, also employ a considerable but a very variable number of agricultural labourers.

Nothing has been done at Rothamsted in the way of manure-, feeding-stuff-, or seed-control.

The investigations may be classed under two heads:-

### I.—FIELD EXPERIMENTS, EXPERIMENTS ON VEGETATION, Etc.

The general scope and plan of the field experiments has been :—  $\,$ 

To grow some of the most important crops of rotation, each separately, year after year, for many years in succession on the same land, without manure, with farmyard-manure, and with a great variety of chemical manures; the same description of manure being, as a rule, applied year after year on the same plot. Experiments on an actual course of rotation, without manure, and with different manures, have also been made. In this way field experiments have been conducted as follows:—

(1) Die landwirthschaftlichen Versuchs-Stationen, Band xxii, 1877.

(2) Rothamsted is in Hertfordshire, twenty-five miles from London, on the Midland Railway; station, Harpenden.

(4)

On Wheat, thirty-eight years in succession; 13 acres, 37 plots, many of which are duplicates of others.

On Barley, thirty years in succession; 41 acres, 29 plots.

On Oats, ten years (including one year fallow);  $\frac{3}{4}$  acre, 6 plots.

On Wheat, alternated with fallow, thirty years; 1 acre, 2 plots.

On different descriptions of Wheat, fourteen years; 4-8 acres (each year in a different field), now more than 20 plots.

On Beans, thirty-two years (including one year Wheat and five years fallow); 1½ acre, 10 plots. Also twenty-seven years; 1 acre. 5 plots.

On Beans, alternated with Wheat, twenty-eight years; 1 acre 10 plots.

On Clover, with fallow or a corn-crop intervening, twentysix years; 3 acres, 18 plots. The land is now devoted to experiments with various Leguminous plants, commenced in 1878.

On Turnips, twenty-eight years (including three years' barley); about 8 acres, 40 plots.

On Sugar Beet, five years; about 8 acres, 41 plots.

On Mangold-Wurzel, six years (in progress); about 8 acres, 41 plots.

On Potatos, six years (in progress); 2 acres, 10 plots.

On Rotation, thirty-four years; about  $2\frac{1}{2}$  acres, 12 plots.

On permanent Grass-land, twenty-six years; about 7 acres, 22 plots.

Comparative experiments with different manures have also been made on other descriptions of soil, in other localities.

Samples of all the experimental crops are taken, and brought to the laboratory. Weighed portions of each are partially dried, and preserved for future reference or analysis. Duplicate weighed portions of each are dried at 100° C., the dry matter determined, and then burnt to ash on platinum sheets in cast-iron muffles. The quantities of ash are determined and recorded, and the ashes themselves are preserved for reference, or analysis.

In a large proportion of the samples the nitrogen is determined; and in some the amount existing as albuminoids, amides, and nitric acid.

In selected cases, illustrating the influence of season, manures, exhaustion, &c., complete ash-analyses have been made, numbering in all more than 600.

Also in selected cases, illustrating the influence of season and manuring, quantities of the experimentally-grown Wheat grain have been sent to the mill, and the proportion and composition of the different mill-products determined.

In the Sugar Beet, Mangold-Wurzel, and Potatos, the sugar in the juice has in most cases been determined by polariscope, and frequently by copper also.

In the case of the experiments on the mixed herbage of permanent grass land, besides the samples taken for the determination of the chemical composition (dry matter, ash, nitrogen, woody fibre, fatty matter, and composition of ash), carefully averaged samples have frequently been taken for the determination of the botanical composition. In this way, on four occasions, at intervals of five years—viz., in 1862, 1867, 1872, and 1877—a sample of the produce of each plot was taken, and submitted to careful botanical separation, and the percentage, by weight, of each species in the mixed herbage determined. Partial separations, in the case of samples from selected plots (frequently of both first and second crops), have also been made in other years.

### INVESTIGATION OF SOILS.

Samples of the soils of most of the experimental plots have been taken from time to time, generally to the depth of 9, 18, and 27 inches, but sometimes to twice this depth. In this way about 600 samples have been taken, submitted to partial mechanical separation, and portions of the mould have been carefully prepared and preserved for analysis. In a large proportion of the samples the loss on drying at different temperatures, and at ignition, has been determined. In most the nitrogen determinable by burning with soda-lime has been estimated. In some the carbon, and in some the nitrogen as nitric acid, have been determined. Some experiments have also been made on the comparative absorptive capacity (for water and ammonia) of different soils and subsoils. The systematic investigation of the amount, and condition, of the nitrogen, and of some of the more important mineral constituents, of the soils of the different plots, and from different depths, is now in progress or contemplated.

#### RAINFALL AND DRAINAGE.

Almost from the commencement of the experiments the rainfall has been measured—for twenty-eight years in a gauge of one-thousandth of an acre area, as well as in an ordinary small funnel-gauge of 5 inches diameter. An 8-inch "Board of Trade" copper gauge is also now in use, commencing January 1, 1881. From time to time the nitrogen, as ammonia and as nitric acid, has been determined in the rain waters. The chlorine has, also, in some cases been determined.

Three "drain gauges," also of one-thousandth of an acre each, for the determination of the quantity and composition of the water percolating respectively through 20 inches, 40 inches, and 60 inches depth of soil (with its subsoil in natural state of consolidation) have also been constructed. A more numerous series of smaller "drain gauges," arranged for the investigation of the influence of different crops, and of different manures, has been constructed; but they have been found to be not sufficiently water-tight. Each of the differently manured plots of the permanent experimental Wheat-field having a separate pipe-drain, the drainage-waters have been and are frequently collected and analysed.

Professor Frankland has determined the nitrogen, as ammonia, as nitric acid, and as organic nitrogen, and also some other constituents, in many samples both of the rain and of the various drainage waters collected at Rothamsted. Dr. Voelcker also has determined the combined nitrogen, and likewise the incombustible constituents, in many of the drainage waters.

The nitrogen existing as nitric acid, sometimes that in other forms, and also some other constituents, are, and for some time past have been, determined periodically, in both the rain and the various drainage waters.

### Amount of Water Transpired by Plants.

For several years in succession, experiments were made to determine the amount of water given off by plants during their growth. In this way various plants, including representatives of the gramineous, the leguminous, and other families, have been experimented upon. Similar experiments have also been made with various evergreen and deciduous trees.

### BOTANICAL CHARACTERISTICS, &c.

Having regard to the difference in the character and amount of the constituents assimilated by plants of different botanical relationships, under equal external conditions, or by the same description of plants, under varying conditions, observations have been made on the character and range of the roots of different plants, and on their relative development of stem, leaf, &c. In the case of various crops, but more especially with Wheat and Beans, samples have been taken at different stages of growth, and the composition determined, in more or less detail, sometimes of the entire plant, and sometimes of the separated parts. In a few cases the amounts of dry matter, ash, nitrogen, &c., in the above-ground growth of a given area, at different stages of development, have been determined. The amounts of stubble of different crops have also occasionally been estimated.

(5)

#### ASSIMILATION OF FREE NITROGEN

Experiments were made for several years in succession to determine whether plants assimilate free or uncombined nitrogen, and also various collateral points. Plants of the gramineous, the leguminous, and of other families were operated upon. The late Dr. Pugh took a prominent part in this inquiry.

### II.—EXPERIMENTS ON ANIMALS, ETC.

Experiments with the animals of the farm were commenced early in 1847, and have been continued, at intervals, up to the present time.

The following points have been investigated:-

- The amount of food, and of its several constituents, consumed in relation to a given live weight of animal within a given time.
- 2. The amount of food, and of its several constituents, consumed to produce a given amount of increase in live weight.
- The proportion, and relative development, of the different organs or parts of different animals.
- 4. The proximate and ultimate composition of the animals in different conditions as to age and fatness, and the probable composition of their increase in live weight during the fattening process.
- 5. The composition of the solid and liquid excreta (the manure) in relation to that of the food consumed.
- 6. The loss or expenditure of constituents by respiration and the cutaneous exhalations—that is, in the mere sustenance of living meat-and-manure-making machine.

The general plan of experimenting was as follows:-

To provide data as to the amount of food, or its several constituents, consumed in relation to a given live weight of animal within a given time, and to produce a given amount of increase in live weight, several hundred animals—oxen, sheep, and pigs—have been experimented upon. Selected lots of animals were supplied, for many weeks, or for months consecutively, with weighed quantities of foods, selected and allotted according to the special point under inquiry. The composition of the foods was determined by analysis. The weights of the animals were taken at the commencement, at intervals during the progress, and at the conclusion of the experiment.

The amount, and relative development, of the different organs and parts were determined in two calves, two heifers, fourteen bullocks, one lamb, 249 sheep, and fifty-nine pigs.

The percentage of water, mineral matter, fat, and nitrogenous substance, were determined in certain separated parts, and in the entire bodies, of ten animals—namely, one calf, two oxen, one lamb, four sheep, and two pigs. Complete analyses of the ashes, respectively, of the entire carcases, of the mixed internal and other "offal" parts, and of the entire bodies, of each of these ten animals have also been made.

From the data provided, as just described, as to the chemical composition of the different descriptions of animal, in different conditions as to age and fatness, the composition of the increase whilst fattening, and the relation of the constituents stored up in increase to those consumed in food, have been estimated.

To ascertain the composition of the manure in relation to that of the food consumed, oxen, sheep, and pigs have been experimented upon.

In the case of oxen, the food and litter (sometimes with an acid absorbent), were weighed, sampled, and analysed; the

animals were fed in boxes, for periods of from five to nine weeks, and the total dung produced was well mixed, weighed, sampled, and analysed. The constituents determined in the food and litter on the one hand, and in the dung on the other, were dry matter, ash, and nitrogen.

In the case of sheep no litter was used; the animals were kept in lots of five, on rafters, through which (but with some little loss) the solid and liquid excreta passed on to a sheet-zing flooring at such an incline that the liquid drained off at once into carboys containing acid, and the solid matter was removed two or three times daily, and also mixed with acid. The constituents determined in the food and manure were dry matter, mineral matter, sometimes woody fibre, and nitrogen.

In the case of pigs, individual male animals were experimented upon, each for periods of three, five, or ten days only. Each animal was kept in a frame, preventing it from turning round, and having a zinc bottom, with an outlet for the liquid to run into a bottle, and it was watched night and day, and the voidings carefully collected as soon as passed, which could easily be done, as the animal never passed either fæces or urine without getting up, and in getting up he rang a bell, and so attracted the notice of the attendant. The constituents determined were, in the food and fæces, dry matter, ash and nitrogen, and in the urine, dry matter, ash, nitrogen, and urea.

The loss or expenditure of constituents, by respiration and the cutaneous exhalations, has not been determined directly, that is by means of a respiration-apparatus, but only by difference, that is, by calculation, founded on the amounts of dry matter, ash, and nitrogen, in the food, and in the (increase) fæces, and urine.

Independently of the points of inquiry above enumerated, the results obtained have supplied data for the consideration of the following questions:—

- 1. The characteristic demands of the animal body (for nitrogenous or non-nitrogenous contituents of food) in the exercise of muscular power.
- 2. The sources in the food of the fat produced in the animal body.
- 3. The comparative characters of animal and vegetable food in human dietaries.

### SUPPLEMENTARY INVESTIGATIONS.

In conjunction with Professor Way, an extensive investigation was undertaken on the application of town sewage to different crops, but especially to grass. The amount, and the composition, of both the sewage and the produce grown were determined; and, in selected cases, the composition of the land drainagewater was also determined. Comparative experiments were also made on the feeding qualities of the differently grown produce; the amount of increase yielded by oxen, and the amount and composition of the milk yielded by cows, being determined. In this inquiry part of the analytical work was performed at Rothamsted, but most of it by Professor Way in London.

The chemistry of the malting process, the loss of food constituents during its progress, and the comparative feeding value of barley and malt, have been investigated.

Although many of the results of the investigations above enumerated have already been published, a large proportion as yet remains unpublished.

(6)

The following lists give the titles of the papers already published, arranged in two series, and within each series arranged in chronological order; and they show in what Journal each paper appeared.

# THE PARK

# MEADOW LAND. WITH DIFFERENT MANURES ON PERMANENT EXPERIMENTS

The Land has probably been laid down with Grass for some centuries. No fresh seed has been artificially sown within the last 40 years certainly; nor is there record or any marking the Grass was first laid down. The experiments commenced in 1886, at which time the character of the horbage appeared uniform over all the Plots. Excepting as explained in the Table, and in the foot-the sheen application of Manuruc has been applicately and very search the first crops only each year, was mown, made into hay, removed from the land, and weighed. As a rule, the second crop was fed-off by sheep having no other food, the object being not to disturb the condition of the amauring. A given number was allotted to each Plot, according to the amount of produce, permed upon a portion of it, and were cut, and spread of aby year, until the whole was eathen down. Frequently, however, the animals suffered considerably, and in 1866, 1877, and 1874, the second crops were cut, and spread on the respective Plots. In the twentieth season, 1875, the second crops were again made into hay, weighted, green; the aty matter in the weighted sand the produce referenced into hay by adding one-fourth to the calculated dry matter per acre. In 1887 and 1875, the second crops were again made into hay, weighed day to the calculated dry matter per acre. In 1886–1875, first crops only, and for the succeeding 5 years, 1876–1880, first and second crops (19).

EXPERIMENTS ON THE GROWTH OF WHEAT YEAR AFTER YEAR ON THE SAME LAND; WITHOUT MANUE, AND WITH DIFFERENT KINDS OF MANUEL.

Previous Cropping—1839, Turnips, with Framyard Manure; 1840, Barley; 1841, Peas; 1842, Wheat; 1843, Oats; the last four Crops Unmanured.

It is a precise to be some proper of the present of the control of the crops of the control of the crops of the present year, 1851, is, therefore, the 38th Wheat Crop in 1845, when the same Plots can't pear—especially during the last 30 years (1852 and rape-cake, &c., if any, were sown in the autumn, before the seed; excepting in 1845, when, owing to the wet autumn and winter, all the manures were spring-sown; and for the experiments and present year, it comes is a spring of the spring. Niture of soda has, however, always been sown in the spring. See the assertained great of the introgen of the amounts by deninge, especially in wet winters, it has been decided to apply only the mineral manures (and Farmyard-manure) in the autumn, and the ammonia-salts, as well as the nitrate, in the spring; excepting on Plot 15, where, for comparison, the ammonia-salts are sown in the autumn. This plan was adopted for the first time for the crop of 1878.

(Area under experiment, about 13 acres.)

\*\*A "A monicalss"—in each case, squal parts Sulphate and Muriate of Ammonia of Commore.

(\*) 550 lbs. Nitrate of Soda is redocated to contain the same amount of Nitrogen as 400 lbs. "A monicassalts."

(\*) On these plots, where large quantities of Nitrate of Soda had been applied year after year, the land, though more worked, was so wet that it could not be got if on the seep plots, where large quantities of Nitrate of Soda had been applied year after year, the land, though more worked, was so wet that it could not be got in yeary interpretation of the land, especially on the Nitrate plots, it was not sown until April 6, and than with a very unfavourable seed bee up very irregularly, and moul of it parished from standing surface-water.

(\*) Owing to the very wet winter, 1876-7, the land could not be worked in time for sowing, and was therefore left fallow in 1877; no manures being applied.

(13)

### EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS.

I .- BEANS, PEAS, AND TARES-GEESCROFT FIELD.

EXPERIMENTS on the growth of Leguminous corn-crops (beans, peas, and tares), with different descriptions of manure, were commenced in 1847, about nine acres being devoted to the purpose.

Experiments with Beans were continued without a break, for thirteen consecutive seasons, to 1859 inclusive; but, during the later years, the crop fell off very much, and the land became very foul.

In 1860 the land was fallowed.
In 1861 a crop of wheat, without manure, was taken.
In 1862 beans were again sown, but with some variation in the manuring.
In 1863 the land was fallowed.

In 1864, 5, 6, 7, 8, and 9, beans were grown, with much the same manures on the same plots, each year, as in 1862.

In the winter of 1869-70, 5000 lbs. of fresh burnt lime were

applied per acre, over all the plots.

In 1870 beans were grown with the same manures on the respective plots as in 1864-69.

In October 1870 winter beans were sown (without manure), but the plants were to so great an extent destroyed by the severe weather which followed, that, in April 1871, the crop

was ploughed up, and the land left fallow.

During the winter and early spring of 1871-2, the land was so wet that it could not be prepared in time for sowing. It was therefore left fallow for 1872; at the end of May it was subsoiled to a depth of about 12 inches, and re-ploughed in July.

The winter and early spring of 1872-3 were also so extremely wet, that it was again impossible to prepare the land in time for sowing; it was, however, ploughed up towards the end of March, again left fallow, and re-ploughed in July and October

(1873). On February 2, 1874, the land was again set with Beans, but without manure.

In 1875 Beans were re-sown, with the same manures on the respective plots as in 1864-1870; but owing to the wet-ness of the land in the first instance, and the subsequent himdrance by other spring sowing, they were not put in until

April 1 and 2.

The wetness of the winter 1875-6, again prevented the preparation of the land in due time; and, though the manures were sown, and the land ploughed, it was left fallow during the summer of 1876.

Early in October, 1876, winter Beans were put in (drilled), without further manuring.

In 1878 the usual manures were sown, and beans were drilled on February 26.

Owing to the wetness of the winter, and the foul condition

of the land, it was left fallow in 1879.

Owing to the continued wetness in the autumn, the severe winter, and foulness of the land, it could not be got into order

During 1880 the land was ploughed, scarified, and partially cleaned, but owing to the wetness of the autumn and the wetness and severity of the winter, it was again impossible to work the land in time for sowing; and it still remains fallow (1881).

The general result of the experiments with Beans has been that mineral constituents used as manure (more particularly potass), increased the produce very much during the early years; and, to a certain extent, afterwards, whenever the season was favourable for the crop. Ammonia-salts, on the other hand, produced very little effect; notwithstanding that a Leguminous crop contains two, three, or more times as much nitrogen as a Gramineous one grown under similar conditions as to soil, &c. Nitrate of soda has, however, produced more marked effects. But Leguminous crops grown too frequently on the same land seem to be peculiarly subject to disease, which no conditions of manuring that we have hitherto tried seem to obviate.

Experiments with Peas were soon abandoned, owing to the difficulty of keeping the land free from weeds, and an alternation

of Beans and Wheat was substituted; the Beans being manured much as in the experiments with the same crop grown continuously as above described. But the wetness of the winter of 1871-72 prevented the sowing of the Beans for the season of 1872; and again the wetness of the autumn and winter of 1872-3 prevented the sowing of the wheat until April 4, 1873, when Nursery wheat was put in, which, however, did not come to maturity, but was cut in the middle of September, yielding about 27 cwts. of gross produce per acre, containing too little corn to be worth thrashing. The land was ploughed in October 1873, and sown with beans February 3, 1874. On October 23, 1874, wheat was sown without manure. Beans should have been sown in 1876; indeed, the manures were sown, but, for the reason stated above, the land was left fallow; and wheat was put in October 24 (1876). In 1878 Beans were drilled, on February 26, with the usual manures. Owing to the wetness of the winter, and the condition of the land, it was left fallow in 1879; and it continues so up to the present time (May 1881).

In alternating Wheat with Beans, the remarkable result had been obtained, that nearly as much wheat, and nearly as much nitrogen, were yielded in eight crops of wheat in alternation with the highly nitrogenous beans, as in sixteen crops of wheat grown consecutively without manure in another field, and also nearly as much as were obtained in a third field in eight crops alternated with bare fallow.

Experiments with Tares, like those with Peas, were soon abandoned, and for the same reasons. Beans were at first substituted, with some variation in the description of the manures employed; but this experiment has likewise been abandoned for some years.

### II .- RED CLOVER (Trifolium prateuse).

### 1. Experiments on ordinary arable land.—Hoos Field.

EXPERIMENTS on the growth of Clover, on ordinary arable land, with many different descriptions of manure, were commenced in 1849, and, with the occasional interposition of a

corn-crop, or fallow, were continued up to 1877, inclusive.

As with other *Leguminous* crops, the result was, that mineral constituents applied as manure (particularly potass) considerably increased the early crops. Ammonia-salts had little or no beneficial effect, and were sometimes injurious. It may be added, that the beneficial effects of long previous applications of potass have been apparent whenever there was any growth at all. To go a little more into detail :-

In the first year, 1849, the crops were throughout very heavy; especially with mineral, and without nitrogenous manure

In autumn 1849 wheat was sown, and in spring 1850 Red Clover. In 1851 small cuttings were taken; and in 1852, though the crops were not heavy, there was by no means a

Since that time, however, all attempts to grow clover year after year on this ordinary arable land have failed to give anything like a full crop, or even a plant which would stand the usual time on the ground.

Small cuttings were obtained in the autumns of 1855 and 1859, from seed sown in the spring of those years; and small but rather heavier cuttings in June and August 1865, from seed sown in 1864.

In April 1868 a portion only of the land was sown with

Clover, and the plant for the most part died off in the winter. In April 1869 the same portion was resown, and gave a small cutting in September of that year; but the plant again died off in the winter

In April 1870 Clover was sown over the whole of the experimental land, this time in conjunction with Barley; but on those portions which had also been sown in 1868 and 1869 the plant again died off during the winter and early spring; whilst from those which had not been sown in 1868 and 1869 two small cuttings were taken in 1871.

### Experiments on the Growth of Leguminous Crops—continued.

In the spring of 1872, the plant being then almost entirely gone, the land was ploughed up. It was again ploughed in July 1872, and in March 1873; the intention being to sow some other Leguminous crop; but owing to the wetness and lateness of the season this was not done; the land was again left fallow, and re-ploughed in the beginning of June and the end

of July (1873).

On May 4, 1874, the land was again ploughed, and sown

On May 4, 1874, the land was again ploughed, and sown

On May 5, without manure. The plant with May 7, 1014, the land was again progned, and sown with Red Clover seed, May 5, without manure. The plant came up well, and was very forward in September, when the flowering stems were cut down, but left on the land. During the winter and early spring the plant on those portions from which cuttings had been taken in 1871 almost entirely failed, and the land was ploughed up in May, and again in August (1875); whilst on those from which none had been taken since 1869 a fair plant remained, and two small cuttings were obtained, namely on June 23, and on August 9 and 12 (1875). On September 22, this portion of the land was

ploughed up. In May (1876) the whole was re-ploughed, again in July and September, and left fallow.

In May 1877, Barley and Clover were sown over the whole

of the experimental Land, without further manuring, but the clover plant completely died off during the winter.

On two occasions (1851 and 1854) heavy dressings of Farmyard dung were applied to some of the plots; and in 1854 some received a dressing of 20 tons of dung, and 5000 lbs. of lime, per acre.

On some portions of the land Clover was sown 12 times during the 30 years, 1848–1877, and more frequently alone than with a corn-crop; but in 9 out of the last 10 trials the plant died off in the winter and spring succeeding the sowing the seed.

In 1878 the land was devoted to experiments with various Leguminous plants, differently manured, and these experiments are still in progress (1881); for further particulars see p. 16.

In reference to these field experiments on clover, it may be added that, in 1864, a portion of the land was trenched 2 feet deep, and one-third of the manure was mixed with the layer from 24 to 16 inches, one-third from 16 to 8 inches, and the remainder from 8 inches upwards. Owing to the characters of the season, the mechanical condition of the land was at first very unfavourable after this treatment; but, although many years have now elapsed, and the excess of constituents supplied was in some cases considerable, the plant has died off as completely on these plots as elsewhere.

Again, in the winter of 1867-8 a number of small beds, each 3 yards × 2, were arranged on the previously unmanured plot of the experimental land. These were dug, some to the depth of 9 inches, some to the depth of 18, some to the depth of 27, and some to the depth of 36 inches, and sown to the respective depths with different mixtures; supplying in some cases very large amounts of potass, soda, lime, magnesia, phosphoric acid, sulphuric acid, nitrate of soda, &c.

From three similar sized beds, the soil was removed to the

depths of 9, 18, and 27 inches respectively, and replaced by soil taken at the same depths from a garden border, on a portion of which Clover had been grown successfully since 1854, as described on the next page.

In April 1868 clover was sown on the whole of these

small beds (as well as on some other portions of the experimental land); but the plant for the most part died off during

the following winter.

In April 1869 the small beds (and the other portions as in 1868) were re-sown, small quantities of clover were cut in Sep-

tember of that year, but the plant again died off in the winter.

In April 1870 Clover was again sown on the small beds in conjunction with barley (as on all the rest of the experimental land), but the plant again died in the winter.

In the spring of 1871 the small beds were again re-sown, and the three with garden-soil were entirely enclosed, both around and above, by galvanised wire netting. Small cuttings were taken from these small beds in July 1872; and (excepting from the beds of garden-soil, which had yielded considerably more than the others in 1872), larger cuttings were taken in July 1873. The produce was the largest where potass and nitrate of soda were employed, and where they were applied in the largest quantity, and to the greatest depths.

In April 1874 there was still some healthy plant on all the beds, but it was considered to be too irregular to preserve. It was, therefore, dug in. The artificially-manured beds were re-manured as before, but only to the depth of 9 inches, and seed was sown on May 4th, July 6th, and October 22nd; each time the plant coming up well, but subsequently dying off. On the three beds of garden-soil, the plant from the first sowing (May 4), for the most part stood; requiring only to be made good here and there on July 6; and in September small cuttings were taken.

More small beds were arranged in the spring of 1874; on which the manures were dug in, at the various depths, on May 11th to 14th, and the seed sown on May 16th. At this time, the wire netting was removed from above the three beds of gardensoil, but the whole series of small beds was now surrounded with netting, to keep out ground game. One series of the new plots received sulphate of potass only, another nitrate of soda only, and a third the two together. The plants came up fairly well, but there were some blanks in the rows, which were re-sown on October 22 (1874). A cutting was taken on June 22 and 23 (1875) from these new beds; the blanks in the rows were re-sown on July 24; a second cutting was taken on August 17; and the blanks were again re-sown on September 22 (1875). The plant was the most even on the beds with sulphate of potass, less so on those with nitrate of soda, and less still on those with both together. The amount of produce was also greater with each of the manures used separately, than with the mixture of the two. In May, 1875, the plant was entirely gone on the old artifi-

re-sowing. On the three beds of garden-soil, though the rows were imperfect, some healthy plants still remained, and gave a small cutting on June 22. On July 24 these beds were dug up; and they, as well as the artificially manured ones just referred to, were re-sown with seed. All came up well, but in May (1876), the plants on the beds of garden-soil were entirely gone, and those on the artificially manured ones nearly so, but they yielded small cuttings on July 17 (1876)

The plants on the new artificially manured beds, like those on the older ones, showed failure in the spring of 1876; but also, like them, gave small cuttings in July. All the small beds were dug up in August (1876); the artificially manured ones remanured as in 1874, the manures dug in to a depth of 9 inches, and seed was sown on September 1, which came up, but the plants died off on all the plots in the winter of 1876-7.

plants died off on all the plots in the winter of 1876-7.

In May 1877, all the small beds were dug up, and sown with Barley and Clover. To try the effects of shelter, the Barley stubble was left unusually high, but the young clover plants completely died off during the winter (1877-8).

In the spring of 1878 the beds were dug up, and cleaned; and they were re-sown with Clover, without further manuring, and they were re-sown with clover, without further manuring.

on June 12 and 13. All came up well, but the plant was almost entirely destroyed by "Fly."

In May 1879, there remained about a quarter of a plant on the plot with the largest amount of mineral manure, including potass, and sown to the greatest depth, and perhaps a third of a plant where the same mineral manures, with nitrate of soda in addition, had been applied; but there was scarcely a single plant on any of the other plots. On June 9 scarcely a single plant of any of the other procs. On June 9 and 10, 1879, all the beds were cleaned, and re-sown with seed, which came up well; but a very wet and cold season following, most of the plants died off during the summer and autumn.

Early in June 1880, all the small beds were cleaned,

and forked up; and on June 10, they were re-sown with seed without further manure. All came up well, but the plants were for the most part destroyed by the severe winter which followed.

In May, 1881, there was perhaps half a plant on two or three only out of the forty small beds; namely, where the mixed mineral manure, including potass, was used without nitrogenous manure; and the greatest vigour was where the manure was applied in the largest quantity, and to the greatest depths. On no other beds (not even on the three made up of garden-soil) was there nearly as much plant; and now (May 1881) all the small beds have been cleaned, the clover plants forked in, manures also forked in, as in 1876, to a depth of 8 or 9 inches, and clover seed sown.

It will be observed that, although in the earlier years, the three small beds in the field which had been artificially made up of surface-soil and subsoil brought from a highly manured

(16)

# EXPERIMENTS WITH VARIOUS LEGUMINOUS PLANTS.-HOOS FIELD.

The land upon which attempts had been made to grow Red Clover in frequent succession since 1849, was devoted to experiments with various Leguminous Plants in 1878; so that the present season, 1881, is the fourth year of those experiments.

The object was to assertain whether, among a selection of plants all belonging to the Leguminous family, but of different habits of growth, and especially of different character and range of reobis, some could be grown successfully for a longer time, and would yield more produce, containing more nitrogen as well as other constituents, than others, all being supplied with the same descriptions and quantities of manuring substances, applied to the surface soil. Further, whether the success in some cases, and the failure in others, would afford additional evidence as to the source of the integer of the Leguminose generally, and as to the causes of the failure of Red Clover in particular, when it is grown too frequently on the same land of the four years. Below, is given a list of the plants now growing (1881), all of which were sown on April 9; and, excepting in the few cases stated, the same doscription has been sown in each of the four years. Below, is given a Table showing the description and quantities of the manures applied to the same plant of the same mineral manure, and on snother a dressing of cow's urine, and on another a charge, on another a dressing of cow's urine, and on another a dressing of cow's urine, and on another and manures, and on conclore a dressing of cow's urine, and on another and manures, and an another a dressing of cow's urine, and an another a dressing of cow's and the drassing and the drassing and the failure in the farmer on three lands, but in the latter 1881. The cowstance on three lands, but in the latter and third years, 1878 and 1880; in the former on three lands, but in the latter and the latter and the same and the same and the latter an

on only two.
is estimated that already several times as much nitrogen has been removed in some of the other plants as in the Red Clover; but it is too soon to form any general conclusions from the results

### EXPERIMENTS ON ROOT-CROPS.—BARN FIELD.

Experiments with Turnips were commenced in 1843. Eight acres, divided into numerous Plots, were set apart for the purpose, and the crop was grown for ten consecutive years on the same land; "Norfolk Whites" 1843–1848, and "Swedes" 1849–1852; on some Plots without manure, and on others with different escriptions of manure. Barley was then grown for three consecutive seasons, 1853–1855, without manure, in order to test the comparative corn-growing condition of the different Plots, and also to equalise their condition, as far as possible, by the exhaustion of some of the most active and immediately available constituents supplied by the previous manuring. A new series of experiments with Swedes was arranged in 1856, having regard to the character of the manures previously applied on the different Plots, and to the results previously obtained. This second series was continued for fifteen years, namely, from 1856 to 1870 inclusive.

The results obtained with Norfolk Whites in the first three years, 1843, 1844, and 1845, were published in the 'Journal of the Royal Agricultural Society of England,' vol. viii. Part II., 1847; and an abstract of the results obtained from 1845 to 1870 inclusive, is given in the Table below.

During the five years, 1871–1875, the land was devoted to experiments with Sugar-Beet, for particulars of which see pp. 18 and 19.

In 1876 experiments with Mangold-wurzel were substituted, and are still in progress (see pages 20 and 21).

mixture is estimated to contain 25 per cent. Ammonia. The 328 lbs. Nitric Acid (Sp. gr. 1°35), mixed with sawdust, and used as a cross-dressing on the Plots of Series 2, from 1858-1860, were estimated to contain Nitrogen = 50 lbs. Amnonia.

(1) The crops of 1839 and 1860 falled, and were ploughed in; but, as the manures were applied, and there would be accumulation within the soil for the succeeding crops, the average produce is calculated as for 15 years, that is the produce of the 13 years is, in each case, divided by 15.

### EXPERIMENTS ON SUGAR BEET (VILMORIN'S GREEN-TOP WHITE SILESIAN)-BARN FIELD.

Grown year after year on the same Land, without Manure, and with different descriptions of Manure, commencing 1871.

Grown year after year on the same Land, without Manuee, and with different descriptions of Manuee, commencing 1871.

Previous Cropping:—1843-'48 (6 Seasons), experiments on Norfolk White Turnips, with different descriptions of Manure.

1849-'52 (4 Seasons), experiments on Swede Turnips, with different descriptions of Manure.

1853-'55 (3 Seasons), Barley without Manure (with a view as far as possible to equalise the condition of the Plots).

1856-'70 (15 Seasons), experiments on Swede Turnips, with different descriptions of Manure, in which the arrangement of the Plots was the same, and that of the Manures very similar—in fact, exactly the same during the last 10 years—as in the first year of Sugar Beet, excepting that, during those 10 years, the Alkalies were omitted for the Swedes. For the second and subsequent years of Sugar Beet slight alterations in the Mineral Manures were made, and in the fourth and fifth years the Farmyard Manure, Nitrate of Soda, Ammonia-salts, and Rape-cake were omitted, as will be seen below. Seed dibbled on the flat; in rows 22 inches apart, and 11 inches apart in the rows; plants moulded up afterwards Roots all carted off, Leaves weighed, spread on the respective Plots, and ploughed in.

Area under experiment about 8 acres. The experiments are arranged as under in 5 Series, each of which comprises 8 Plots

<sup>(1) &</sup>quot;Superphosphate of Lime"—in all cases made from 200 lbs. Bone-ash, 150 lbs. Sulphuric Acid sp. gr. 1-7 (and water).

(2) "Ammonia-salts"—in each case equal parts Sulphate and Muriate of Ammonia of Commerce.

(3) Owing to the deficiency of Rain for some time after sowing a large proportion of the plants failed.

Some were transplanted on plots 1, but not on the other plots; and eventually the plant was (excepting on plots 1) upon the whole very deficient and irregular, the remaining plants being larger than usual.

(19)

### EXPERIMENTS ON SUGAR BEET-BARN FIELD-continued.

### SUMMARY OF THE COMPOSITION OF THE SUGAR-BEET ROOTS.

As it will be some time before we shall be able to report fully the results obtained illustrating the influence of different manures, and different seasons, on the composition of Sugarbeet, an abstract of the analytical results obtained is given below. In interpreting the figures it must be borne in mind that with forty different experiments each year, and in each year 4 or 5 or more times as much produce on some plots as on others, it would be impossible to sample each at its best, and all in the same condition of ripeness. Each year the seed was sown on all the Plots at the same time; and the samples (each consisting of the vertical fourths of 10 or 15 roots) were taken from all within a period of about a week, beginning with the ripest. It is obvious, however, that the smaller crops would be much riper than the larger ones. The dry matter, ash, and nitrogen, as given in the table, are determined in the roots themselves; but they have generally been determined in the expressed juice also. The sugar is determined in the juice; and calculated into its percentage in the roots, on the assumption that they contain uniformly 95 per cent. of juice. But, with roots varying so much in character of growth, size, and ripeness, this to recent experiments of Schiebler, and others, however, the percentage of the juice in the roots, respectively, has been over-estimated. According to these new results, the amount of true juice will average more nearly 90, than 95 per cent. If this be established, the percentage of sugar in the roots will be less (perhaps \frac{1}{15} to \frac{1}{15} best) than given in the Table below.

(1) Owing to the deficiency of Rain for some time after sowing a large proportion of the plants failed. Some were transplanted on plots 1, but not on the other plots; and eventually the plant was (excepting on plots 1) upon the whole very deficient and irregular, the remaining plants being larger than usual.

(19)

### EXPERIMENTS ON SUGAR BEET-BARN FIELD-continued.

#### SUMMARY OF THE COMPOSITION OF THE SUGAR-BEET ROOTS.

As it will be some time before we shall be able to report fully the results obtained illustrating the influence of different manures, and different seasons, on the composition of Sugarbeet, an abstract of the analytical results obtained is given below. In interpreting the figures it must be borne in mind that with forty different experiments each year, and in each year 4 or 5 or more times as much produce on some plots as on others, it would be impossible to sample each at its best, and all in the same condition of ripeness. Each year the seed was sown on all the Plots at the same time; and the samples (each consisting of the vertical fourths of 10 or 15 roots) were taken from all within a period of about a week, beginning with the ripest. It is obvious, however, that the smaller crops would be much riper than the larger ones. The dry matter, ash, and nitrogen, as given in the table, are determined in the roots themselves; but they have generally been determined in the expressed juice also. The sugar is determined in the juice; and calculated into its percentage in the roots, on the assumption that they contain uniformly 95 per cent. of juice. But, with roots varying so much in character of growth, size, and ripeness, this will not be the case. Nevertheless, the results so calculated, approximately, and usefully, represent both the actual and relative amounts of sugar in the various roots. According to recent experiments of Schiebler, and others, however, the percentage of the juice in the roots, respectively, has been over-estimated. According to these new results, the amount of true juice will average more nearly 90, than 95 per cent. If this be established, the percentage of sugar in the roots will be less (perhaps \( \frac{1}{3}\) to \( \frac{1}{20}\) less) than given in the Table below.

It need only further be observed that although, in comparable cases, the larger crops generally give a juice containing a lower percentage of sugar, and higher percentages of mineral matter and of nitrogen, yet the larger

(1) Owing to the deficiency of Rain for some time after sowing a large proportion of the plants failed. Some were transplanted on plots 1, but not on the other plots; and eventually the plant was (excepting on plots 1) upon the whole very deficient and irregular, the remaining plants being larger than usual.

( 20 )

EXPERIMENTS ON MANGOLD WURZEL.—BARN FIELD (after Sugar-beet); commencing 1876.

The arrangement of the Plots is precisely the same as previously for Sugar-beet, excepting that Plot 9, which was unmanured for Sugar-beet, and also previously for Swedes, is now added as a manured Plot. With this exception, the manures are also substantially the same as previously for Sugar-beet; in fact, precisely the same as for the Sugar-beet in 1872 and 1873. Seed, Yellow Globe; dibbled on ridges, rows 26 inches apart; plants 11 inches apart in the rows (3). Area under experiment about 8 acres. Roots all carted off; Leaves weighed, spread on the respective Plots, and ploughed in.

### EXPERIMENTS ON MANGOLD WURZEL .—BARN FIELD—continued.

### SUMMARY OF THE COMPOSITION OF THE MANGEL ROOTS.

Summary of the Composition of the Mangel Roots.

As it will be some time before we shall be able to report fully the results obtained, or to be yet obtained, illustrating the influence of different manures, and of different seasons, on in the roots themselves. The sugar is determined in the expressed juice; and calculated into its percentage in the roots, on the assumption that they contain uniformly 96 per cent. represent both the actual and relative amounts of sugar in the various roots. According to the recent experiments of Schiebler, and others, on Sugar-beet, the percentage of and supposing them to apply to mangolds, the amount of true juice would average not much more than 90, instead of 96 per cent.; and if so the percentage of sugar in the roots, expensions of given in the roots, perhaps from \( \frac{1}{3}\times \) \( \frac{1}{3}\times \) less) than given in the Table below. The amounts of dry matter, ash, and nitrogen, are of course determined of juice. But, with roots varying so much in character of growth, size, and ripnease, this will not be the case. Nevertheless, the results so calculated, approximately, and usefully, juice in the roots, reckoned from the determined percentage of dry matter in the juice, and in the roots, respectively, has been over-estimated. According to these new results, will be less (perhaps from \( \frac{1}{3}\times \) \( \frac{1}{3}\times \) less) than given in the Table below. The amounts of dry matter, ash, and nitrogen, have also, in many cases, been determined an as nitric acid. It may be observed that by far the larger proportion of both the mineral matter and the nitrogen of the roots is found in the juice; and of the nitrogen in Interpreting the figures, it must be borne in mind, that, with forty different experiments each year, and, in each year four, or five, or more, times, as much produce on some plots sample analysed was in each case a mixture of vertical sections of ten or fifteen roots, and all the samples were as a rule taken within a period of from one to

### EXPERIMENTS ON POTATOS.—HOOS FIELD; commencing 1876.

The Land had been under experiments with Wheat, differently manured, from 1856 to 1874; and was fallowed in 1875.

Plots 1, 2, 3, and 4 had been unmanured for the Wheat. Plots 5 and 6 had received the same quantity of Ammonia-salts alone every year for the Wheat, as Plot 5 now receives for potatos: Plot 6 now receiving the same amount of nitrogen, but as Nitrate of Soda, instead of Ammonia-salts. Plots 7 and 8 received the same amount of complex mineral manure, and Ammonia-salts, for the Wheat, as Plot 7 now receives for potatos; and Plot 8 now receives the same complex mineral manures, and the same amount of nitrogen, but as Nitrate of Soda instead of Ammonia-salts. Plots 9 and 10 received the same complex mineral manures alone for the Wheat as Plot 10 now receives for potatos; Plot 9 now receives superphosphate only (3). Description of Potatos, in 1876, 1877, 1878, and 1879, the "Rock;" and in those years the rows were 25 inches apart; with 12 inches from plant to plant in the rows. In 1880 and 1881, the description was the "Champion;" and the rows were 25 inches apart; with 14 inches from plant to plant in the rows.

<sup>(7) &</sup>quot;Ammonia-salts"—in each case equal parts Sulphate and Muriate Ammonia of Commerce.

(3) The complex mineral manure having been sown in October, 1874, but the Wheat not put in, and therefore no crop taken in 1875, no mineral manures are sown afresh on Plots 7, 8, 9, and 10, for the first crop of potatos, 1876.

( 23 )

### EXPERIMENTS ON POTATOS.—HOOS FIELD—continued.

### SUMMARY OF THE COMPOSITION OF THE "GOOD" TUBERS.

Summary of the Composition of Potatos, an abstract of some of the analytical results at present at command is given below. The specific gravity of the tubers is also given. In the tubers the dry matter, nitrogen, and ash have been determined; and in some cases complete analyses of the ash have been made. Besides the results obtained relating to the composition of the tubers themselves, the dry matter, the sugar, the nitrogen, and the ash in the expressed juice have in many cases been determined; in some cases the amount of the nitrogen existing as albumenoids has been determined; and in some, complete analyses of the ash of the juice have been made. It may be remarked, that by far the larger proportion of both the mineral matter, and the nitrogen, is found to exist in the juice; and of the nitrogen in the juice, as a rule, not much more than half exists as albuminoids. In the majority of cases, the small potatos have been submitted to the same methods of analysis as the good potatos. And in a large number of cases, similar methods of examination have been applied to the still white, and also to the separated discoloured portions of the discoloured portion contained very much less. On the other hand, the washed, or exhausted "mark" of the white portion, contained very little nitrogen, whilst that of the discoloured portion contained very much more. The distribution of the mineral matter was much in the same order as that of the nitrogen. It was obvious that the juice had suffered exhaustion of much of both its nitrogen and its mineral matter, in the development of the fungus. There was an increased amount of sugar found in the diseased potatos, the result of diseased action, and it probably also contributed to the development of the fungus. There was an increased amount of sugar found in the diseased potatos, the result of diseased action, and it probably also contributed to the development of the fungus.

The results given in the Table relate to the "good" potatos only. In interpreting the figures it must be bo

Chat	ge from the original weight of the samples, the results being calculated upon the fresh weights as mainly take			Composition	of the "God	nd " Tubers

### AGDELL FIELD.

EXPERIMENTS ON AN ACTUAL COURSE OF ROTATION—TURNIPS, BARLEY, LEGUMINOUS CROP (OR FALLOW), AND WHEAT.

Experiments on an actual Course of Rotation—Turnips, Barley, Leguminous Crop (or Fallow), and Wheat.

These Experiments were commenced in 1848; so that the present crop (1881) is the 34th experimental one, or the second crop of the Ninth Course. One-third of the land has been continuously unmanured; one-third manured with Superphosphate of Lime alone once every four years, that is for the turnip-crop commencing each course; and one-third manured (also for the turnip-crop only) with a complex manure, as described in the foot-note, No. 2.

In the Second, Third, and Fourth Courses, clover was sown, but failed; and in them, and in the Fifth and Sixth Courses, beans were taken instead, on half of each plot, and the other half left failow; for the third crop of the Seventh Course clover was again sown (spring 1873), on half of each plot, and gave three cuttings in 1874; the other half of each being left failow. In the Eighth Course beans were again grown. For the Ninth Course (Spring 1881) clover has been sown.

From half of each of the three plots the whole turnip-crop (roots and leaves) was removed; and on the other half the roots were eaten on the land by sheep, and the uneaten leaves spread and ploughed in. In the case of all the other crops, the total produce was removed from the land.

The abstract of the results given below relates to the portions of each plot from which the turnip-crops were entirely removed; and on which, in the second, third, fourth, fifth, sixth, and eighth courses, beans (not fallow) replaced the clover.

(Area under experiment, about 23 acres.)

### FARM.

1881.

CROPPING, &c., OF THE ARABLE LAND NOT UNDER EXPERIMENT.

inclusive.

AND MANURING.					Crops, &c., Present Season,	Acres.	Name of Field.	
1876.	1877.	1878.	1879.	1880.	1880-'81.			
Grass (¾), Compost. Wheat (¼), 1 cwt. Nitrate Soda.	Grass (‡), Cattle Grazed. Barley (‡), 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Grass (\frac{2}{3}), Cattle Grazed with Cotton-Cake. Tares (\frac{1}{2}), Dung.	Grass (‡), Cattle Grazed with Cotton-Cake. Barley (‡), 2 cwts. superphosphate, 2 cwts. Nitrate Soda.	Grass (2), Cattle Grazed with Cotton-Cake. Fallow (1).	Grass (‡), Cattle Grazed with Cotton- Cake, Hay, and Mangolds. Oats (‡), 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	30	Thirty Acre	
Wheat (Varieties), 2 cwts. Nitrate Soda.	Barley, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Barley (with Clover), 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Clover, Unmanured. One Crop as Hay.	Wheat (½), (Varieties). 50 bushels Soot. Mangolds (½), 15 tons Dung & 3 cwts. Guano. (Carted off).	Fallow (½). Wheat (½), 1½ cwts. Nitrate Soda.	22	. Harpender	
Barley, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda (½ with Clover).	Barley, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda (½ with Clover).	Barley $(\frac{1}{2})$ , $2\frac{1}{2}$ ewts. superphosphate, $2\frac{1}{2}$ ewts. Nitrate Soda. Clover $(\frac{1}{2})$ , Unmanured. Two Crops as Hay.	Barley, 2 cwts. superphosphate, 2 cwts. Nitrate Soda.	Barley, 2½ cwts. Guano.	Barley,  2½ cwts. superphosphate,  2½ cwts. Nitrate Soda.  (½ with Clover).	9	Little Hoo	
Barley, 2½ cwts, superphosphate, 2½ cwts. Nitrate Soda.	White Turnips, Dung. Superphosphate, ½ cwt. Nitrate Soda; part fed, part carted.	Wheat (Varieties). 2 cwts. Nitrate Soda,	Barley, 2 cwts. superphosphate, 2 cwts. Nitrate Soda.	Barley, 2½ ewts. Guano.	Fallow,	18	Fosters'.	
Oats, 21 cwts. superphosphate, 3 cwts. Nitrate Soda.	Barley, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Roots (½). Dung and Artificial. (Carted off). Fallow (½).	Wheat (½), 2 ewts. Nitrate Soda. Barley (½), 2 ewts. superphosphate, 2 ewts. Nitrate Soda (all with Clover).	Barley (\frac{1}{2}), 2\frac{1}{2} ewts. Guano. Clover (\frac{3}{2}), Unmanured. (\frac{3}{2}) 2 crops as Hay, (\frac{1}{2}) 1 crop as Hay, aftwds. Fed.	Wheat,	30	Knott Woo	
Oats, 2½ cwts. superphosphate, 3 cwts. Nitrate Soda.	Oats (with Clover), 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Clover, Unmanured. First and second Crops as Hay; afterwards fed.	Wheat (Varieties), 2 cwts. Nitrate Soda.	Barley, 2½ cwts. Guano.	Oats, $2\frac{1}{2}$ cwts. Nitrate Soda, $2\frac{1}{2}$ cwts. superphosphate.	}14	Little Kno Wood.	
Mangolds, 25 tons Dung. (Carted off.)	Wheat (Varieties), 1 <sup>3</sup> cwt. Nitrate Soda.	Barley, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Barley, 2 cwts. superphosphate, 2 cwts. Nitrate Soda.	Fallow.	Mangolds, (½) Dung 16 tons in 1880, 4 cwts. Guano in 1881, (½) Dung, 18 tons in 1881,	14	Sawpit.	
Swedes, Dung, and Superphosphate.	Barley, 1 cwt. Nitrate Soda.	Barley, 2½ cwt. superphosphate, 2½ cwts. Nitrate Soda.	Barley (3), 2 cwts. superphosphate, 2 cwts. Nitrate Soda. Fallow (4),	Mangolds, 15 tons Dung, 3 cwts. Guano. (Carted off.)	Wheat, (Varieties), 1½ cwt. Nitrate Soda.	8	Rick-yard	
Barley, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Barley (with Clover), 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Clover, Unmanured. Two Crops as Hay.	Wheat, 2 cwts, Nitrate Soda.	Mangolds, 15 tons Dung, 3 cwts. Guano. (Carted off.)	Wheat,	}6	Six Acres,	
Oats, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Fallow.	Wheat, 2 cwts, Nitrate Soda.	Barley, 2 cwts. superphosphate, 2 cwts. Nitrate Soda.	Barley, 2½ cwts. Guano.	Fallow.	12	Clay-Croft	
Fallow.	Wheat (with Clover), 2 cwts. Nitrate Soda.	Clover, Unmanured. Two Crops as Hay.	Barley, 2 cwts. Nitrate Soda (with Grass Seeds).	Grass, Unmanured.	Grass. Cattle Grazed, with Cotton-Cake. Dung 15 tons.	10	Ten Acres	
Barley, 2½ cwts. superphosphate, 3 cwts. Nitrate Soda. Swedes, 3 acres, Experiment.	Barley, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda. Barley, 3 acres Experiment.	Potatos, Dung and Artificial. (3 acres Experiment ½ Beans, ½ Fallow.)	Barley, 2 cwts. superphosphate, 2 cwts. Nitrate Soda (3 acres Experiment, Wheat).	Fallow, (3 acres Experiment, Swedes).	Oats, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda, (3 acres Experiment, Barley).	9	Agdell.	
$\begin{array}{c} \textbf{Oats} \ (\frac{3}{2}), \\ 2\frac{1}{2} \text{ cwts. superphosphate,} \\ 3 \text{ cwts. Nitrate Soda.} \\ \textbf{Tares} \ (\frac{1}{4}), \\ \textbf{Dung.} \end{array}$	Barley, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	Barley, $2\frac{1}{2}$ cwts. superphosphate, $2\frac{1}{2}$ cwts. Nitrate Soda.	Barley, 2 cwts. superphosphate, 2 cwts. Nitrate Soda.	Barley, 2½ cwts. Guano.	Barley, (with Clover).  2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	25	Long Hoo	
Barley (with Clover), 2 cwts. superphosphate, 2 cwts. Nitrate Soda.	Barley $(\frac{3}{4})$ , $2\frac{1}{2}$ cwts. superphosphate, $2\frac{1}{2}$ cwts. Nitrate Soda.  Tares $(\frac{1}{4})$ , Dung.	Barley. (3) 2½ cwts. superphosphate, 2½ cwts. Nitrate S.da, (1) 2½ cwts. Nit. Soda alone.	Roots $(\frac{1}{3})$ , 25 tons Dung, 1 cwt. Nitrate Soda (Carted off); Fallow $(\frac{2}{3})$ .	Wheat, 50 bushels Soot.	Mangolds, Dung 20 tons.	25	Sawyers'.	
Oats, 2 cwts, superphosphate, (3) 1½ Nitrate Soda, (4) 2½ Nitrate Soda.	Fallow.	Wheat, 2 cwts. Nitrate Soda.	Winter Oats, 2 cwts. Nitrate Soda.	Barley, 50 bushels Scot.	Barley, 2½ cwts. superphosphate, 2½ cwts. Nitrate Soda.	30	West Bar
